

SECTION 1.2

STATIONARY DIESEL ENGINES (Non-Agricultural Engines)

(Issued September 15, 2003)

EMISSION INVENTORY SUMMARY CATEGORY

Stationary Sources - Fuel Combustion

EMISSION INVENTORY CODES (CES CODES) AND DESCRIPTION

099-040-1200-0000 (89664) Stationary Non-Agricultural Engines - Diesel

EXECUTIVE SUMMARY

To support development of the Air Toxic Control Measure (ATCM) for stationary diesel engines, ARB staff worked with local air districts to develop a single statewide methodology and updated population and emission estimates for these engines. Equipment types considered include air compressors, prime and backup generators, prime and backup pumps, and other miscellaneous stationary diesel engines. Population and emission estimates for agricultural irrigation engines were not included in this methodology.

Based on this methodology, ARB estimates that in the year 2002 there were approximately 21,000 stationary diesel-fueled engines statewide. Backup generators was the most common stationary diesel equipment type (56%), followed by backup pumps (37%), prime generators (3%), prime pumps (2%), and others (1%). Air compressors were found to be primarily portable and therefore were a negligible stationary source category, both in terms of population and emissions. Allocation of engines to local air districts relied on human population as a surrogate. Consequently, over 85% of the statewide stationary diesel engine population was attributed to the following five districts: South Coast AQMD, Bay Area APCD, San Joaquin Valley Unified APCD, San Diego APCD, and Sacramento AQMD. We are aware that our district-specific estimates do not always agree with district estimates; however, this discrepancy will be addressed as the ATCM is implemented.

ARB estimates that in 2002, stationary diesel-fueled engines in California emitted 1.1 tons per day of diesel PM. In addition, those engines are estimated to have emitted 20.3 tons per day of oxides of nitrogen (NOx), 1.8 tons per day of reactive organic gases (ROG), and 6.9 tons per day of carbon monoxide (CO). Although backup engines make up over 50% of the stationary diesel engine population, they contribute less than 20% of the overall emissions due to their relatively low annual hours of operation. On the other hand, due to their relatively high number of hours of operation, prime generators and prime pumps are estimated to contribute the majority of stationary diesel engine emissions (35% and 23%, respectively). In the future, ARB estimates that the population of stationary diesel-fueled engines will increase at a rate roughly proportional to the

rate of human population growth but that emissions will decrease due to the implementation of the stationary diesel ATCM.

BACKGROUND

In October 2000, the California Air Resources Board (ARB) published the Risk Reduction Plan to Reduce Particulate Matter Emissions from Diesel-fueled Engines and Vehicles. That plan outlined a strategy for the reduction of diesel particulate matter (PM) by 75 percent by 2010 and by 85 percent by 2020. Sources of diesel PM include stationary sources, portable sources, on-road sources, and off-road sources (excluding the portable sources).

To meet the diesel PM emission reduction goals set forth in the diesel risk reduction plan, the ARB began the process of drafting air toxic control measures (ATCMs). ATCMs are regulatory in nature. Essential components of any regulation being developed are the cost effectiveness component and the regulatory effectiveness component. Essential to those components is a comprehensive and accurate emission inventory.

This methodology estimates the statewide population and emissions for stationary non-agricultural diesel engines, including air compressors, generators, pumps, and other types of equipment. Stationary engines associated with agricultural processes are not included in this emission estimation method. Estimation of the population and emissions from agricultural engines is described in an April 30, 2003 California Air Resources Board (ARB) memorandum entitled "Updated Statewide Population and Emission Inventory for Diesel-Fueled Agricultural Irrigation Pumps" (see Attachment G).

Stationary non-agricultural diesel engines are assumed to be engines that remain at a facility for at least 12 months, regardless of whether the engine is on wheels or a skid. Stationary diesel engines range in horsepower from less than 15 horsepower to over 3000 horsepower.

The stationary diesel engine inventory presented here is based upon reconciliation of district permit data for selected districts and Power Systems Research (PSR) data for all districts. The methodology allows the development of a more comprehensive and representative stationary diesel engine emission inventory, as additional data become available.

METHODS AND SOURCES

Engine Population

The population of stationary diesel engines was estimated for the following equipment types: air compressors, generators (prime and backup), pumps (prime and backup), and others (including crushers, grinders, cranes, and others).

The stationary diesel engine population was based on population estimates originally described in the ARB's OFFROAD model database of non-road mobile diesel engines. The OFFROAD population estimates were developed from nationwide engine sales data provided by PSR in 1996 and the ARB Stationary Source Division (SSD) Portable Equipment Database.

PSR is an independent research firm involved in research and development related to engine and engine component industries. The PSR database contains North American engine sales data compiled between 1989-1996 and reports engine populations by equipment type to the statewide level. The ARB staff estimated county-specific engine populations by spatially allocating the statewide PSR data using year 2002 county-specific human population data from the California Department of Finance (see Attachment A). The engine population for the year 2002 reported here was estimated using PSR 1996 engine population estimates that were grown to the year 2002 using growth and control surrogates found in the OFFROAD model.

501-750	0.1	0.9
>750	0.1	0.9

Data Source: "Off-Road Mobile Equipment Emission Inventory Estimate", Booz Allen & Hamilton (BAH), January 1992

The PSR database does not differentiate between mobile and stationary engines. To estimate the number of stationary diesel engines, mobile-stationary splits by horsepower class were applied to the overall inventory of diesel engines reported by PSR. These mobile-stationary splits, which are shown in Table 1 (page 3), are based on a report published by Booz-Allen & Hamilton in 1992.

The majority of small horsepower diesel engines are assumed to be mobile while most large horsepower engines are assumed to be stationary. The OFFROAD model supplied the mobile diesel engine population estimates based

on the PSR database, and the relative fractions of stationary to mobile engines were used to estimate the stationary engine population. The resulting OFFROAD-PSR stationary diesel engine population is shown in Table 2 (page 4). A complete listing of this data, broken down by County, Air Basin, and District, is contained in Attachment D.

Data Sources: Mobile ARB OFFROAD Model; Stationary - this methodology

Based on a telephone survey of local air districts, review of district permit data, and discussions with engine distributors, ARB staff concluded there are very few stationary diesel air compressors statewide and that the majority should be classified as portable equipment. Of the estimated statewide population of 8,452 air compressors shown in Table 2 (page 4), the ARB staff telephone survey found five air compressors that were considered stationary. These engines were left out of the horsepower reallocation described here because there were so few of them and they were specifically identified by location and size.

ARB conducted a similar telephone survey of district staff and reviewed district permit data to verify the numbers of "Other" engines that the PSR database assumed to be stationary (Table 2). The PSR data identified most of those engines as welders or pressure washers. The ARB survey indicated that the vast majority of those engines designated as "Others" were portable and should be designated as such. The revised numbers of "Other" engines is also reflected in Table 9 (page 17). The "Other" engine survey population was further split by county, air basin, and district using the Department of Finance human population data found in Attachment A. Like the air compressors, these engines were left out of the horsepower reallocation because there were so few of them and they were specifically identified by location and size.

In an effort to verify the stationary engine population estimates estimated using the OFFROAD-PSR database, the ARB staff compared the OFFROAD-PSR estimates with diesel engine permit information in local air district files. Since there is no comprehensive statewide permit database of stationary diesel engines, permit data from the following districts was solicited: Sacramento Metropolitan Air Quality Management District (SMAQMD), San Diego County Air Pollution Control District (SDCAPCD), San Joaquin Valley Unified Air Pollution Control District (SVUAPCD), and South Coast Air Quality Management District (SCAQMD). These districts were selected because they permit prime and back-up engines and their engine populations reflect a representative mix of urban and agricultural applications. Combined, these four districts represent approximately 58% of the stationary non-agricultural diesel engine population in California.

Total	7241	13312
Includes Sacramento, San Joaquin Unified, San Diego, and South Coast Districts		
* 669 engines greater than 750 hp		

Table 3 (page 5) compares the stationary engine population estimates by horsepower class developed for those four districts based on the OFFROAD-PSR database and district permit files. For the four districts considered, the total number of stationary non-agricultural diesel engines in district permit files (7,241 engines) is approximately 54% of the total number of engines predicted by the PSR data (13,312 engines) for those districts. The discrepancies between the district permit data and the OFFROAD-PSR population estimate varies based on the horsepower class considered. For engines less than 750 hp, permit files contain 4,899 engines or 39% of the 12,643 engines predicted by the

OFFROAD-PSR database. For engines greater than 750 hp, permit files contain 2,342 engines or three and one half times of the 669 engines predicted by the OFFROAD-PSR database.

District permit data indicates that the horsepower range distribution of the OFFROAD-PSR data does not represent the actual horsepower range distributions for stationary engines found in California, particularly for large engines. For example, the PSR data does not estimate engines greater than 750 horsepower but the available district permit data shows that at least 10 percent of permitted engines are greater than 750 horsepower. For this emission inventory update, the district permit data was assumed to be more representative of the numbers of large engines (greater than 750 hp), and the OFFROAD-PSR data were used to allocate smaller engines (less than 750 hp).

One of the shortcomings of the OFFROAD-PSR data is that it cannot be used to determine the principal way an engine is used, particularly generators and pumps. The OFFROAD-PSR data does not segregate generators and pumps into their prime and backup uses. Prime and backup engines are used in significantly different ways and therefore have different emission rates. The district permit data were used to address this issue and serve as a template to distribute the baseline populations of generators and pumps by principal usage.

To differentiate between prime and backup generators and pumps, the ARB staff analyzed district permit data and engine data from the California Energy Commission for the four districts listed above. Since the data for the Sacramento Metropolitan Air Quality Management District and the San Diego Air Pollution Control District was the most recent and complete, composite percentages were developed using the data from those two districts. The numbers of prime and backup engines were recorded for each district and totaled. That resulted in a ratio of five percent prime to ninety-five percent backup for both generators and pumps.

The ratio of the number of 750 hp or greater permitted engines to the total number of engines in the baseline database was used to split the original baseline population at 750 hp. This ratio was developed using only data from districts for which both permit and OFFROAD-PSR data was available (i.e. SMAQMD, SDCAPCD, SJVUAPCD, SCAQMD). The relative horsepower class ratios of baseline engines less than 750 hp (Table 4, page 7) and the relative horsepower class ratios of permitted engines greater than 750 hp (Table 5, page 7) were then used to further allocate engines amongst the horsepower classes for all districts. Tables 4 and 5 (page 7) show the horsepower classes and the ratios used to allocate the baseline population. The composite engine horsepower distribution is shown in Table 6 (page 8).

Table 4
OFFROAD-PSR Engine Population

Total	20694		100%	20694	100%

After engines were distributed among counties, equipment types, and horsepower ranges, they were allocated by age using the diesel engine age distribution shown in Attachment B. The age distribution for prime engines is identical to the one used in the ARB's OFFROAD model. For backup engines, analysis of district permit data indicated that backup engines tend to be in use much longer than prime engines. This analysis showed that backup engines can be up to 50 years old, and approximately 20% of backup engines are at least 20 years old. This information was used to adjust the age distribution for prime engines to create a composite age distribution for backup engines.

The population of stationary engines for a specific equipment type, horsepower range, and model year can be estimated using the following steps:

Step 1. This step is necessary to estimate the numbers of stationary engines based on the total number engines associated with the OFFROAD-PSR national engine population data.

$$\text{Pop}_{et,ss,dis} = \text{Sum} (\text{Pop}_{et,hp,ms,dis} * \text{Frac}_{hp,ss} / \text{Frac}_{hp,ms})$$

Where: $\text{Pop}_{et,ss,dis}$ = Stationary engine population for equipment type et in District dis .

$\text{Pop}_{et,hp,ms,dis}$ = Mobile engine population (from PSR database) for equipment type et , horsepower hp for District dis . (see Table 2, page 3)

$\text{Frac}_{ss,hp}$ = Fraction of engines of horsepower hp that are stationary (see Table 1, page 2)

$\text{Frac}_{ms,hp}$ = Fraction of engines of horsepower hp that are mobile (see Table 1, page 2)

Step 2. This step is necessary to estimate the numbers of engines by horsepower class.

$$\text{Pop}_{et,hp,ss,dis} = \text{Pop}_{et,ss,dis} * \text{Frac}_{hp}$$

Where: $\text{Pop}_{et,hp,ss,dis}$ = Stationary engine population for equipment type et of horsepower hp in District dis .
 $\text{Frac}_{et,hp}$ = Fraction of horsepower class hp engines (from Table 6, page 7)

Step 3. This step is necessary to estimate the numbers of prime versus backup engines in each horsepower class.

$$\text{Pop}_{((pr,ba),hp,ss,dis)} = \text{Pop}_{et,hp} * \text{Frac}_{(pr,ba)}$$

Where: $\text{Pop}_{(pr,ba),hp,ss,dis}$ = Stationary engine population of either prime or backup engines for equipment type et of horsepower hp in District dis .
 $\text{Pop}_{et,hp}$ = Total stationary engine population of given equipment type et and horsepower class hp (pumps or generators only)
 $\text{Frac}_{(pr,ba)}$ = Fraction of either prime or backup equipment for given equipment type from district permit data

Step 4. This step is necessary to estimate the numbers of engines of a particular horsepower class that belong to a specific model year. Knowing the model year is essential to assigning emission factors for a specific subset of engines.

$$\text{Pop}_{et,my,ss,dis} = \text{Pop}_{et,by,hp,dis} * \text{AD}_{my}/100$$

Where: $\text{Pop}_{et,my,ss,dis}$ = Stationary engine population for equipment type et , model year my in District dis .
 $\text{Pop}_{et,by,hp,dis}$ = Stationary engine population for equipment type et , base year by , horsepower class hp in District dis .
 AD_{my} = Percent Age Distribution for model year my (from Attachment B).

Sample Calculations:

Population:

Population of 1988 model year backup generators between 250 and 500 horsepower in base year 2002, Los Angeles County, South Coast Air Basin, South Coast AQMD:

Step 1.

$$\text{Pop}_{et,hp,my,ss} = \text{Sum}(\text{Pop}_{et,hp,by,ms} * \text{AD}_{my} * \text{Frac}_{hp,ss} / \text{Frac}_{hp,ms})$$

(see table 7 below, data from Attachment E, page D-19)

Table 7

OFFROAD-PSR Data for Generator Sets in Los Angeles County, South Coast Air Basin, South Coast AQMD					
Horsepower Class	$\text{Pop}_{et,hp,by,ms}$	$\text{Frac}_{hp,ss}$	$\text{Frac}_{hp,ms}$	$\text{Frac}_{hp,ss} / \text{Frac}_{hp,ms}$	$\text{Pop}_{et,hp,by,ss}$
	(from Offroad-PSR database)	(from Table 1)		(calculated)	(calculated)
0-25	2453	0	1	0.00	0
25-50	1267	0.1	0.9	0.11	141
50-120	1959	0.3	0.7	0.43	840
120-175	79	0.8	0.2	4.00	316
175-250	90	0.85	0.15	5.67	512
250-500	120	0.9	0.1	9.00	1081
500-750	29	0.9	0.1	9.00	257
>750	29	0.9	0.1	9.00	257
Total Generator Sets for Los Angeles County, South Coast Air Basin, South Coast AQMD					3404

Step 2.

$$\text{Pop}_{et,hp,ss,dis} = \text{Pop}_{et,ss,dis} * \text{Frac}_{hp}$$

$\text{Pop}_{et,ss,dis} = 3404$ (from step 1)

$\text{Frac}_{250-500} = 0.2906$ (from Table 6, page 8)

$\text{Pop}_{et,et,hp,ss,dis} = 2842 * 0.2906 = 989.4$ generator sets between 250 and 500 hp

Step 3.

$$\text{Pop}_{(pr,ba)} = \text{Pop}_{et} * \text{Frac}_{(pr,ba)}$$

$\text{Pop}_{et} = 989.4$ generator sets (from step 2)

$\text{Frac}_{(pr,ba)} = 0.95$ backup generators (see text)

$\text{Pop}_{(pr,ba)} = 989.4 * 0.95 = 939.9$ backup generators between 250 and 500 hp.

Step 4.

$$\text{Pop}_{et,my,ss,dis} = \text{Pop}_{by,et,hp,dis} * \text{AD}_{my}$$

$\text{Pop}_{by,et,hp,dis} = 989$ engines (from Step 3)

$\text{AD}_{my} = 3.77\%$ (value for 1988, from Attachment B)

$\text{Pop}_{et,my,ss,dis} = 989 * 3.77/100 = 37.28$ backup generators, 1988 model year, in Los Angeles County, South Coast Air Basin

Emission Estimations

Activity Data

The average horsepower, load factor and activity (as a function of the annual hours of operation) vary by engine type and by horsepower range for each equipment type. Assumptions for each are shown in Attachment C.

“Average horsepower” is the average rated horsepower (assumed to be constant by calendar year) based on the assumption that the power demand for an equipment type does not change with time. The values used in this methodology are from the PSR database for engines less than 750 hp and from district permit data for engines greater than 750 hp.

“Load factor” is the average operation level for a given application expressed as a percent of the engine manufacturer’s maximum horsepower rating. It has been assumed in the 1996 PSR database that engine type will operate at an average load factor. The load factor is used to adjust the maximum rated horsepower to horsepower levels under day-to-day operating conditions.

“Activity” is the measure of an engine type’s average annual hours of operation. For most engine types, the 1996 PSR database is the source of engine activity data, but because there was no specific activity data available for prime and backup generators or pumps, ARB survey data described immediately below is used to estimate activities for backup generators and backup pumps.

The ARB conducted a number of surveys of District permitted engines to gather specific information about prime and backup engines operating in California. From these surveys, the ARB staff was able to develop activity data for prime generators and pumps, as well as backup generators and pumps. The annual activity for backup generators and pumps is assumed to be thirty (30) hours per year. The activity data for prime engines was also based on survey data. The annual activity for prime generators and prime pumps assumed to be 953 hours per year (the average for all prime engines responding to the ARB’s survey of prime engine owner/operators). Attachment A shows the activities that were assigned to all equipment classes.

Emission Factors

Emission factors (Attachment D) were obtained from Appendix A of the ARB’s OFFROAD Model Documentation (Reference 1). They are based on the U.S. Environmental Protection Agency’s adopted diesel standards and reflect California regulations. These emission factors are for certified engines only, however; there is no requirement that commercial diesel engines meet certification requirements. Accordingly, it was assumed that when new engine standards come into effect, there will be low compliance level with certified engine emission standards, since purchasers of new commercial diesel engines can legally opt to buy uncertified engines. It was further assumed that as time

goes on, more and more new engines will meet the certified emission standard. Accordingly, the certified emission factors shown in Attachment D were weighted in such a manner that emission factors descend gradually rather than descend suddenly when new emission standards are implemented.

The emission factors are composed of zero-hour (new equipment) emissions and deterioration rates. The emission factors can be expressed by the following equation:

$$EF_{et,hp,my,pol} = ZH_{et,hp,my,pol} + DR_{et,hp,my,pol} * CHrs_{et,hp}$$

Where: $EF_{et,hp,my,pol}$ = emission factor, in grams per horsepower-hour (g/hp-hr) for equipment type et , horsepower hp , model year my , and pollutant pol .

$ZH_{et,hp,my,pol}$ = zero-hour emission rate, or when the equipment is new (g/hp-hr) for equipment type et , horsepower h , model year my , and pollutant pol .

$DR_{et,hp,my,pol}$ = deterioration rate, or the increase in ZH emissions as the equipment is used (g/hp-hr²) for equipment type et , horsepower hp , model year my , and pollutant pol .

$CHrs_{et,hp}$ = cumulative hours, or total number of annual hours of use for equipment type et , horsepower hp , and model year my .

The zero-hour emission rates and the deterioration rates are shown in Attachment B. These factors vary by engine horsepower rating and model year only. They are the same factors used in the OFFROAD model for estimating emissions from non-road mobile diesel engines.

The cumulative hours of operation are calculated by multiplying the age of the engine (the model year) by the activity, or the number of hours per year that the engine operates. The activity varies by equipment type and is shown in Attachment A. The activities assumed for stationary diesel engines are the same as those assumed in the OFFROAD model for non-road mobile diesel engines.

Emissions per day are calculated using the following equation:

$$\text{EMS}_{\text{TOTAL}} = \text{Sum}(\text{EMS}_{et,hp,my})$$

Where:

et-equipment type (air compressors, generators, pumps, and other);

hp-horsepower range;

my-model years considered (1970 through 2002 (32 years total))

$$\text{EMS}_{et,hp,my} = \text{EF}_{et,hp,my} * \text{HP}_{et} * \text{LF}_{et,hp} * \text{Activity}_{et,hp} * \text{CF} * \text{Pop}_{et,hp,my}$$

Where:

$\text{EMS}_{et,hp,my}$ = amount of pollutant in tons per day (tons/day) for equipment type *et*, horsepower *hp*, and model year *my*.

$\text{EF}_{et,hp,my}$ = emission factor in grams per horsepower-hour (g/hp-hr) for equipment type *et*, horsepower *hp*, and model year *my*.

HP_{et} = Maximum rated average horsepower for equipment type *et*.

$\text{LF}_{et,hp}$ = Load factor for equipment type *et* and horsepower *hp*

$\text{Activity}_{et,hp}$ = annual activity in hours per year (hr/yr) for equipment type *et* and horsepower *hp*

CF = conversion factor to convert units of grams per year to tons per day

$\text{Pop}_{et,hp,my}$ = Number of engines of type *et*, horsepower *hp*, and model year *my*.

Sample Calculations:

Emission Factor:

Base Year 2002 NOx Emission Factor for backup generators between 250 and 500 horsepower, Model Year 1988, Los Angeles County, South Coast Air Basin, South Coast AQMD

$$\begin{aligned} EF_{et,hp,my,pol} &= ZH_{et,hp,my,pol} + DR_{et,hp,my,pol} * CHrs_{et,hp} \\ CHrs_{et,hp} &= (\text{Base Year} - \text{Model Year}) * \text{Activity} \end{aligned}$$

Where: $ZH_{et,hp,my,pol}$ = zero-hour emission rate, in g/hp-hr = 11.0 g/hp-hr, 1987 factor (from Attachment D)

$DR_{et,hp,my,pol}$ = deterioration rate, in g/hp-hr = 0.000183 (from Attachment D)

Base Year = 2002

Model Year = 1988

Activity = 30 hours/year (from Attachment B)

$CHrs_{et,hp}$ = cumulative hours = (base year – model year)*Activity
= (2002 – 1988=14 years) * 30 hours/year = 420 hours

$EF = ZH + DR * CHrs = 11.0 + 0.000183 * 420 =$

$EF = 11.1 \text{ gm/hp-hr}$

Emissions:

2002 NOx Emissions for backup generators between 250 and 500, Model year 1988, Los Angeles County, South Coast Air Basin, South Coast AQMD:

$$EMS_{et,hp,my} = EF_{et,hp,my} * HP_{et} * LF_{et,hp} * Activity_{et,hp} * CF * Pop_{et,hp,my}$$

Where: $EF_{et,hp,my}$ = 11.1 gm/hp-hr (from above)

HP_{et} = 363 hp (from Attachment C)

$LF_{et,hp}$ = 0.74 (from Attachment C)

$Activity_{et,hp}$ = 30 hours/year (from Attachment C)

CF: 1 gram/year = (0.0000011 ton/year)/365 days/year = 3.0137E-09 tons/day

$Pop_{et,hp,my}$ = 37.3 engines (1988 model year, see above)

$$EMS_{et,hp,my} = 11.1 \text{ gm/hp-hr} * 363 \text{ hp} * 0.74 * 30 \text{ hours/year} * 3.0137E-09 \text{ ton/day} * 37.3 \text{ engines}$$

$$\mathbf{EMS_{et,hp,my} = 0.0100 \text{ tons/year}}$$

Forecasting Population and Emissions to 2002

The year 2002 engine populations provided in this methodology were grown using the OFFROAD model, based on the 1996 PSR engine populations. The growth surrogates used in the OFFROAD model were obtained from a 1994 study by California State University, Fullerton (CSUF) entitled "A Study to Develop Projected Activity for Non-Road Mobile Categories in California, 1970-2020". For non-agricultural diesel engines, the surrogates used were a combination of projected employment growth and change in human population. The CSUF growth surrogates were used for all of the local air districts, with the exception of Bay Area Air Quality Management District and South Coast Air Quality Management District, who provided their own growth estimates.

Forecasting Population and Emissions Beyond 2002

Future year engine populations and emissions for the years 2010 and 2020 were estimated using the methodology set forth in the documentation for the OFFROAD model (Reference 6). The emissions projections provided in this methodology reflect both growth and control assumptions for future years. Because forecasted employment growth surrogates previously used were not available, county-specific human populations from the Department of Finance (DOF) were used as a growth surrogate in developing the stationary diesel engine populations. Based on the most recent DOF data, human population is projected to increase statewide at 1.7% per year between the years 2002 and 2020. Growth rates vary by county and this is reflected in the emission projections provided in this methodology. Control assumptions reflected in the emission projections include current federal and state emission standards.

The only exception to the growth scenarios is for South Coast AQMD. South Coast Rule 1110.2 establishes strict NOx emissions limits whose net effect is that no new prime diesel engines will be permitted in the South Coast AQMD beginning in 2003. In developing 2010 and 2020 emissions projections for the South Coast, it was therefore assumed that no new prime engines would enter the fleet between 2003 and 2020.

RESULTS

As shown in Table 9 (page 18), it is estimated there are 20,983 stationary non-agricultural diesel engines in California. Of these, the majority are backup generators and backup pumps (11,909 and 7,750 engines, respectively). Of the remaining stationary engines, 627 are prime generators, 408 are prime pumps, 5 are air compressors, and 284 are other (including crushers, grinders, cranes, turbine starters, and others). As shown in Table 10 (page 19), over 85% of the statewide stationary diesel engine population is found in the following five districts: South Coast AQMD, Bay Area APCD, San Joaquin Unified APCD, San Diego APCD, and Sacramento AQMD.

Emissions of ROG, NOx, PM, and CO by district and stationary diesel engine equipment type are shown in Table 11 (page 20). ROG, NOX, PM, and CO emissions from these engines are estimated to be 1.8, 20.3, 1.1, and 6.9 tons per day, respectively. The majority of the emissions occur in those districts with the largest stationary diesel engine populations. A detailed breakdown of engine population and emissions by district, air basin, county, equipment type, and horsepower class is provided in Attachment E.

Forecasted emissions for 2005, 2010, 2015, and 2020 are shown in Table 12 (page 21). Despite increases in the number of engines, emissions decline in future years due to the introduction of new emission controls for non-road engines by the US Environmental Protection Agency and the California Air Resources Board. Taking into account the growth and control assumptions described previously. Table 12 shows that emissions from nonagricultural stationary diesel engines are projected to decline by 58%, 46%, 49%, and 63% between the years 2005 and 2020 for ROG, NOX, CO, and PM, respectively. The percent emission reductions vary by equipment type because of South Coast AQMD rule 1110.2 (see above) and methodological differences in the development of the “other” equipment population.

We believe that the statewide total engine population and emissions estimates presented here are the most accurate possible based on data available at this time. We recognize that the district-specific engine population and emissions estimates presented in this methodology may not agree with those of the districts. This is due to the necessity of using county-specific human population as a spatial surrogate to allocate statewide engine populations to specific districts. We are aware that the current spatial surrogate does not reflect the possibility that rural areas may have a higher percentage of stationary diesel engines for a given population. Specifically, it is likely that our engine population estimates may be low for rural districts such as the Mojave Desert AQMD and high for urban districts such as the South Coast AQMD and the San Diego APCD. We intend to resolve the majority of the uncertainties and apparent discrepancies in the district-specific estimates as the Stationary Diesel ATCM is implemented and more detailed engine count data become available.

MEMORANDUM

TO: Randy Pasek, Chief, Emission Inventory Branch

FROM: Michael Benjamin, Manager, Emission Inventory Systems Section

DATE: March 27, 2003

SUBJECT: **Updated Agricultural Irrigation Pump Emission Inventory**

With the assistance of local air district staff, we have updated the statewide emission inventory for diesel-fueled agricultural irrigation pumps. Agricultural irrigation engines (EIC 052-042-1200-0000) is one of the area source categories for which the local air districts are responsible for estimating emissions. As part of this update process, we contacted seventeen air districts with significant irrigated agricultural acreage to obtain their best estimates of the current population and emissions from stationary and mobile diesel-fueled agricultural irrigation engines. The revised statewide population and emission estimates are provided in Table 1. We estimate there are approximately 8,200 diesel-fueled agricultural irrigation pumps statewide that emit 4.7 tons per day (tpd) of ROG, 48.9 tpd of NOx, and 3.7 tpd of PM on an average summer day.

Specific to the San Joaquin Valley, the updated information differs from that recently discussed by the Emission Inventory Subcommittee of the California Air Resources Board Agriculture Advisory Committee for Air Quality. As directed by the Subcommittee on February 19, we have worked with staff from the San Joaquin Valley UAPCD to explicitly account for the benefits of the Carl Moyer Program. As you can see in Table 2, although the number of pumps in the SJV has increased, the overall emissions have not changed significantly since we also revised our assumptions about the number of operating hours and emission factors. We will be providing the EI Subcommittee with a written report that will discuss in greater detail the assumptions used in developing the revised inventory for the SJV.

The energy challenge facing California is real. Every Californian needs to take immediate action to reduce energy consumption. For a list of simple ways you can reduce demand and cut your energy costs, see our Website: <http://www.arb.ca.gov>.
